Q: Elegant way to access nested properties and fields in JavaScript Is there a more elegant way of accessing nested properties and fields (properties of a property) in JavaScript? (Notice that the nested properties or fields are different from the properties of a property of an object, as they can be (are) fields of an object, too.) In Ruby one can use the following syntax: `object.property.another_property` or `object.property.another_property.another_property` To access a field of the first nested property one would do: `object.property.another_property.property_of_an_object.field` Is there an elegant way to do this in JavaScript? A: There are different methods to achieve this: 1)

`object["property_name"]["another_property"]["field_name"]` 2)

`object.property.another_property.field_name` 3)

`object["property_name"]["another_property"]["field_name"]` 4)

`Object.getOwnPropertyDescriptor(object, "property_name")["another_property"]["field_name"]`

An organometallic complex that consists of a mononuclear complex in which two weakly coordinating ditopic ligands are chelated to a silver(I) atom has been synthesized. A detailed analysis of the electronic structure of the complex has been carried out using density functional theory, with the characterization of its ground state and three low-lying excited states. The unusual electronic structure of the complex is due to the possibility of a weak interaction between the metal center and the surface, arising from the pi-acceptor character of the ditopic ligands. In particular, the highest energy electronic state that we have identified corresponds to a metal-to-ligand charge transfer (MLCT) excitation. The apparent absence of any electronic correlation effects in the higher energy states is due to the weak metal-ligand interaction and the limited relaxation energy of the ligands. The unusual electronic structure of this compound and the fact that it is stable is very unusual and the first example of such an organometallic complex.
