relates to a process for removing sulfurous and other compounds from a liquid hydrocarbonaceous feedstock, such as a natural gas stream or a crude petroleum distillate fraction.

More particularly, the present invention relates to the use of a selective oxidation process for the removal of carbon monoxide, carbonyl sulfide, and hydrogen sulfide from a liquid hydrocarbonaceous feedstock such as a natural gas stream or crude petroleum distillate fraction. Sulfur compounds in the liquid hydrocarbonaceous feedstocks are of great importance. For example, carbonyl sulfide (COS) is a primary contributor to the "rotten egg" odor of natural gas. Hydrogen sulfide (H_2S) is also of importance because it reacts with metals to form poisonous sulfides which have a deleterious effect on refinery processes and apparatus. Thus, if left in the feedstock, the sulfur compounds will lower the energy content and the value of the feedstock, and will cause corrosion in refinery processes and equipment, and they will interfere with various catalytic processes. Further, the sulfur compounds are a source of sulfuric acid in the presence of water, and therefore should be removed from the feedstock.

In addition to these obvious disadvantages, there are environmental problems in the presence of sulfur compounds in the gas stream. For example, the sulfur compounds may react with atmospheric nitrogen and result in sulfur dioxides
