This model has a structure that allows the convenient generation of an arbitrary number of clones. Subsequent generations are taken as new spatial coordinates, whose values are calculated by taking the fractional composition values of each of the former clones into account. The model is a two-dimensional array in which the cells are distributed in a square lattice. Each cell carries two parameters that characterize its behavior: an attractor (1) and its value (2). When each cell is randomly assigned a value, a spatial pattern that reproduces the original model is formed. This model takes advantage of an iterative process that alternates between the following two actions: (1) the algorithm that evaluates the value of the cells of the lattice, and (2) the modification of the values of the cells, according to the following rules: The attraction is determined by a *saturation rule*. If the global saturation value of the lattice is reached, the cells have a tendency to approach the closest attractor. The value of each cell is recalculated after every iteration. If the difference between the current and the previous values of a cell is smaller than a fixed value (*error tolerance*), the change in value is performed without any further reference to the other cells. The error tolerance was set equal to 10^{-6} . !**Schematic representation of the microinjection algorithm**. The distribution of the *Y*(1) parameter in a grid of lattice cells (bottom) is simulated by randomly distributing the cells in the lattice and assigning to each cell a value from a uniform distribution with a range of values (values in the range from 0 to 1). The grid is iteratively divided into a succession of clusters (top). The process stops when the final number of clusters is reached.](fnana-08-00067-g0006){#F6} The starting configuration, as well as the values of 2d92ce491b
